### The neuron

The sigmoid equation is what is typically used as a transfer function between neurons. It is similar to the step function, but is continuous and differentiable.

Figure: The Sigmoid Function

### The neuron

The sigmoid equation is what is typically used as a transfer function between neurons. It is similar to the step function, but is continuous and differentiable.

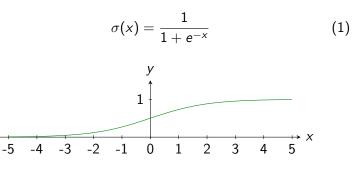

Figure: The Sigmoid Function

One useful property of this transfer function is the simplicity of computing it's derivative. Let's do that now...

$$\frac{d}{dx}\sigma(x) = \frac{d}{dx}\left(\frac{1}{1+e^{-x}}\right)$$

$$\frac{d}{dx}\sigma(x) = \frac{d}{dx}\left(\frac{1}{1+e^{-x}}\right)$$
$$= \frac{e^{-x}}{(1+e^{-x})^2}$$

$$\frac{d}{dx}\sigma(x) = \frac{d}{dx}\left(\frac{1}{1+e^{-x}}\right)$$
$$= \frac{e^{-x}}{(1+e^{-x})^2}$$
$$= \frac{1+e^{-x}-1}{(1+e^{-x})^2}$$

$$\frac{d}{dx}\sigma(x) = \frac{d}{dx}\left(\frac{1}{1+e^{-x}}\right) \\ = \frac{e^{-x}}{(1+e^{-x})^2} \\ = \frac{(1+e^{-x})-1}{(1+e^{-x})^2}$$

$$\frac{d}{dx}\sigma(x) = \frac{d}{dx}\left(\frac{1}{1+e^{-x}}\right)$$
$$= \frac{e^{-x}}{(1+e^{-x})^2}$$
$$= \frac{(1+e^{-x})-1}{(1+e^{-x})^2}$$
$$= \frac{1+e^{-x}}{(1+e^{-x})^2} - \frac{1}{(1+e^{-x})^2}$$

- t<sub>j</sub> : Target value of node j of the output layer

### The error calculation

Given a set of training data points  $t_k$  and output layer output  $\mathcal{O}_k$  we can write the error as

$$E = rac{1}{2} \sum_{k \in K} (\mathcal{O}_k - t_k)^2$$

We let the error of the network for a single training iteration be denoted by *E*. We want to calculate  $\frac{\partial E}{\partial W_{jk}^{\ell}}$ , the rate of change of the error with respect to the given connective weight, so we can minimize it.

Now we consider two cases: The node is an output node, or it is in a hidden layer...

 $\frac{\partial E}{\partial W_{jk}} =$ 

$$\frac{\partial E}{\partial W_{jk}} = \frac{\partial}{\partial W_{jk}} \frac{1}{2} \sum_{k \in \mathcal{K}} (\mathcal{O}_k - t_k)^2$$

$$\frac{\partial E}{\partial W_{jk}} = (\mathcal{O}_k - t_k) \frac{\partial}{\partial W_{jk}} \mathcal{O}_k$$

$$\frac{\partial E}{\partial W_{jk}} = (\mathcal{O}_k - t_k) \frac{\partial}{\partial W_{jk}} \sigma(x_k)$$

$$\frac{\partial E}{\partial W_{jk}} = (\mathcal{O}_k - t_k)\sigma(x_k)(1 - \sigma(x_k))\frac{\partial}{\partial W_{jk}}x_k$$

$$rac{\partial E}{\partial W_{jk}} = (\mathcal{O}_k - t_k)\mathcal{O}_k(1 - \mathcal{O}_k)\mathcal{O}_j$$

$$rac{\partial E}{\partial W_{jk}} = (\mathcal{O}_k - t_k)\mathcal{O}_k(1 - \mathcal{O}_k)\mathcal{O}_j$$

For notation purposes I will define  $\delta_k$  to be the expression  $(\mathcal{O}_k - t_k)\mathcal{O}_k(1 - \mathcal{O}_k)$ , so we can rewrite the equation above as

$$\frac{\partial E}{\partial W_{jk}} = \mathcal{O}_j \delta_k$$

where

$$\delta_k = \mathcal{O}_k(1 - \mathcal{O}_k)(\mathcal{O}_k - t_k)$$

 $rac{\partial E}{\partial W_{ij}} =$ 

$$rac{\partial E}{\partial W_{ij}} = rac{\partial}{\partial W_{ij}} rac{1}{2} \sum_{k \in K} (\mathcal{O}_k - t_k)^2$$

$$\frac{\partial E}{\partial W_{ij}} = \sum_{k \in K} (\mathcal{O}_k - t_k) \frac{\partial}{\partial W_{ij}} \mathcal{O}_k$$

$$\frac{\partial E}{\partial W_{ij}} = \sum_{k \in K} (\mathcal{O}_k - t_k) \frac{\partial}{\partial W_{ij}} \sigma(x_k)$$

$$\frac{\partial E}{\partial W_{ij}} = \sum_{k \in K} (\mathcal{O}_k - t_k) \sigma(x_k) (1 - \sigma(x_k)) \frac{\partial x_k}{\partial W_{ij}}$$

$$\frac{\partial E}{\partial W_{ij}} = \sum_{k \in K} (\mathcal{O}_k - t_k) \mathcal{O}_k (1 - \mathcal{O}_k) \frac{\partial x_k}{\partial \mathcal{O}_j} \cdot \frac{\partial \mathcal{O}_j}{\partial W_{ij}}$$

$$\frac{\partial E}{\partial W_{ij}} = \sum_{k \in K} (\mathcal{O}_k - t_k) \mathcal{O}_k (1 - \mathcal{O}_k) W_{jk} \frac{\partial \mathcal{O}_j}{\partial W_{ij}}$$

$$rac{\partial {m{\mathcal{E}}}}{\partial W_{ij}} = rac{\partial \mathcal{O}_j}{\partial W_{ij}} \sum_{k \in \mathcal{K}} (\mathcal{O}_k - t_k) \mathcal{O}_k (1 - \mathcal{O}_k) W_{jk}$$

$$\frac{\partial E}{\partial W_{ij}} = \mathcal{O}_j(1-\mathcal{O}_j)\frac{\partial x_j}{\partial W_{ij}}\sum_{k\in\mathcal{K}}(\mathcal{O}_k-t_k)\mathcal{O}_k(1-\mathcal{O}_k)W_{jk}$$

$$rac{\partial E}{\partial W_{ij}} = \mathcal{O}_j(1-\mathcal{O}_j)\mathcal{O}_i\sum_{k\in K}(\mathcal{O}_k-t_k)\mathcal{O}_k(1-\mathcal{O}_k)W_{jk}$$

$$rac{\partial {m{\mathcal{E}}}}{\partial W_{ij}} = \mathcal{O}_j(1-\mathcal{O}_j)\mathcal{O}_i\sum_{k\in \mathcal{K}}(\mathcal{O}_k-t_k)\mathcal{O}_k(1-\mathcal{O}_k)W_{jk}$$

But, recalling our definition of  $\delta_k$  we can write this as

$$\frac{\partial E}{\partial W_{ij}} = \mathcal{O}_i \mathcal{O}_j (1 - \mathcal{O}_j) \sum_{k \in K} \delta_k W_{jk}$$

$$rac{\partial E}{\partial W_{ij}} = \mathcal{O}_j(1-\mathcal{O}_j)\mathcal{O}_i\sum_{k\in\mathcal{K}}(\mathcal{O}_k-t_k)\mathcal{O}_k(1-\mathcal{O}_k)W_{jk}$$

But, recalling our definition of  $\delta_k$  we can write this as

$$rac{\partial \mathcal{E}}{\partial \mathcal{W}_{ij}} = \mathcal{O}_i \mathcal{O}_j (1 - \mathcal{O}_j) \sum_{k \in \mathcal{K}} \delta_k \mathcal{W}_{jk}$$

Similar to before we will now define all terms besides the  $O_i$  to be  $\delta_i$ , so we have

$$\frac{\partial E}{\partial W_{ij}} = \mathcal{O}_i \delta_j$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 = のへで

How weights affect errors

For an output layer node  $k \in K$ 

$$\frac{\partial E}{\partial W_{jk}} = \mathcal{O}_j \delta_k$$

where

$$\delta_k = \mathcal{O}_k(1 - \mathcal{O}_k)(\mathcal{O}_k - t_k)$$

For a hidden layer node  $j \in J$ 

$$\frac{\partial E}{\partial W_{ij}} = \mathcal{O}_i \delta_j$$

where

$$\delta_j = \mathcal{O}_j(1 - \mathcal{O}_j) \sum_{k \in \mathcal{K}} \delta_k W_{jk}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

#### What about the bias?

If we incorporate the bias term  $\theta$  into the equation you will find that

$$rac{\partial \mathcal{O}}{\partial heta} = \mathcal{O}(1-\mathcal{O}) rac{\partial heta}{\partial heta}$$

◆□▶ ◆□▶ ◆∃▶ ◆∃▶ = のへで

and because  $\partial \theta / \partial \theta = 1$  we view the bias term as output from a node which is always one.

#### What about the bias?

If we incorporate the bias term  $\theta$  into the equation you will find that

$$rac{\partial \mathcal{O}}{\partial heta} = \mathcal{O}(1-\mathcal{O}) rac{\partial heta}{\partial heta}$$

and because  $\partial \theta / \partial \theta = 1$  we view the bias term as output from a node which is always one.

This holds for any layer  $\ell$  we are concerned with, a substitution into the previous equations gives us that

$$\frac{\partial E}{\partial \theta} = \delta_{\ell}$$

(ロ) (同) (E) (E) (E) (O)(O)

(because the  $\mathcal{O}_{\ell}$  is replacing the output from the "previous layer")

### The back propagation algorithm

- 1. Run the network forward with your input data to get the network output
- 2. For each output node compute

$$\delta_k = \mathcal{O}_k (1 - \mathcal{O}_k) (\mathcal{O}_k - t_k)$$

3. For each hidden node calulate

$$\delta_j = \mathcal{O}_j(1 - \mathcal{O}_j) \sum_{k \in K} \delta_k W_{jk}$$

4. Update the weights and biases as follows Given

$$\Delta W = -\eta \delta_\ell \mathcal{O}_{\ell-1}$$
  
 $\Delta heta = -\eta \delta_\ell$ 

apply

$$W + \Delta W \rightarrow W$$
  
 $\theta + \Delta \theta \rightarrow \theta$
